I find it scientifically interesting. I find PA's natural history interesting, and encouraging (if we can come back from THAT to where we are today, where can we be tomorrow?). But I still enjoy reading the old stories of before some of these areas were decimated, of wild trout in places where we couldn't even dream of it today. Knowledge helps everyone, whether its immediately apparant or not.

No, it does not matter personally for me. From a management perspective, I'm not sure. If it were proved there are none, then I don't think anything changes. If someone proved there were a genetically original strain somewhere, which could happen, then perhaps there could be an extra effort to protect them.

I'm hoping Tups will answer the question about his motivations. I think it is about something more than interesting natural history to him, based on his statements.
